### (54) Packet-based binary convolutional codes

(57) A 64-state binary convolutional code is disclosed for a high-speed physical layer (PHY) of a communication network. The proposed code provides improved performance in terms of signal to noise ratio (SNR) and multi-path rejection than previously known codes. The proposed system, which includes binary convolutional codes with scrambling in a packet-based

system, is referred to herein as "packet binary convolutional coding" (PBCC). The substantial increase in performance that may be achieved by PBCC makes it an ideal solution for high performance forward error correction (FEC) in a high-speed PHY.

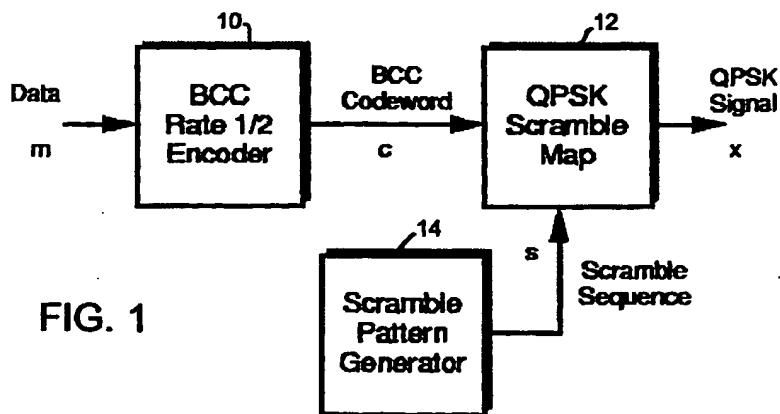

FIG. 1

**Description**

[0001] This application claims the benefit of U.S. provisional application no. 60/098,089 filed on August 27, 1998.

5 **FIELD OF THE INVENTION**

[0002] The present invention relates to convolutional coding for data communications, and more particularly to a convolutional code that is scrambled by a pseudo-random (PN) sequence to rotate selected, transmitted symbols by 90 degrees.

10 **BACKGROUND OF THE INVENTION**

[0003] Current network communications systems generally utilize a layered, packet-based approach for transmitting data, although a non-packet based (i.e., continuous) data format may also be used. In such networks, the purpose of each layer is to offer particular services to the higher layers. Each layer is shielded from the details of how the services are actually implemented. The lowest layer is the physical layer (PHY), which is concerned with transmitting raw bits over a communication channel. The goal of the physical layer is to make sure that when the transmitted bit is a "1", it is decoded by the receiver as a "1" and not as a "0", and vice-versa.

[0004] One technique for communicating data over the physical layer is known as trellis coded modulation (TCM). TCM is a combined Forward Error Correction (FEC) coding and modulation scheme that utilizes an underlying convolutional code applied to certain bits of M-ary Phase Shift Keyed (MPSK) or M-ary Quadrature Amplitude Modulation (MQAM) symbol mappings. The utility of TCM is in providing an increased data rate over bandlimited channels using straightforward decoding hardware. See, e.g., Viterbi, Andrew et. al., "A Pragmatic Approach to Trellis-Coded Modulation," *IEEE Communications Magazine*, July 1989, pp. 11-19.

[0005] Currently, various convolutional codes are under discussion for use in a high-speed PHY that operates, e.g., at a carrier frequency of 2.4. GHz. It would be advantageous to introduce such a code that produces improved performance in terms of signal to noise ratio (SNR) and multi-path rejection. The provision of such a code would advantageously allow the high-speed PHY to be used in a greater range of applications than would be possible with previously proposed techniques, such as complementary code key (CCK) modulation.

[0006] It would be further advantageous to provide a binary convolutional code that generates sufficient gain to enable improved range, improved throughput, and reduced transmission delay. Moreover, an encoder for such a code should have low computational complexity. Still further, it would be advantageous if the mechanism for using such a code would be similar to the multi-rate mechanism already provided for supporting optional rates set forth in the IEEE 802.11b wireless local area network standard.

[0007] The present invention provides a binary convolutional code having the aforementioned and other advantages.

**SUMMARY OF THE INVENTION**

[0008] In accordance with the present invention, a method is provided for convolutionally encoding digital data for transmission over a communication channel. In a first embodiment, the data are processed using a 64-state, rate  $\frac{1}{2}$  binary convolutional code based on octal generators 133, 175 to provide binary convolutional coded codewords. The codewords may be scrambled prior to transmission over the communication channel.

[0009] In a preferred embodiment, the codewords are encoded jointly onto in-phase (I) and quadrature (Q) channels. The codeword bits are mapped to a constellation according to a binary pseudo-random scramble sequence (also referred to as a cover sequence). In the event that a bit of the scramble sequence corresponding to a particular codeword bit has a binary value of, e.g., zero, the constellation is maintained in a current relationship with respect to the constellation axes. In the event that the corresponding bit of the scramble sequence has the opposite binary value (e.g., one), the constellation is rotated by ninety degrees, e.g., in a counterclockwise direction.

[0010] The scramble sequence can be generated from a seed sequence such as the sequence 0011001110001011, where the first bit of the sequence in time is the left most bit.

[0011] Apparatus is disclosed for encoding data for use in digital communications systems. The apparatus includes a binary convolutional encoder and a scrambler for scrambling codewords provided by the encoder prior to transmission over a communication channel. In an illustrated embodiment, the scrambler is responsive to a scramble pattern generator.

[0012] In a second embodiment, the data are processed using a 64-state, rate 2/3 binary convolutional code based on octal generators

$$\begin{pmatrix} 21,02,12 \\ 10,25,12 \end{pmatrix}$$

5

to provide binary convolutional coded codewords.

#### DETAILED DESCRIPTION OF THE INVENTION

[0014] The present invention provides a method and apparatus for encoding data for use in digital communications systems. More particularly, a binary convolutional coding (BCC) scheme with a 64-state binary convolutional code and a scramble sequence is disclosed. It is noted that schemes with other codes (e.g., an N-state BCC) can also be provided in accordance with the invention. The output of the BCC is encoded jointly onto corresponding in-phase (I) and quadrature (Q) communication channels, as further documented hereinafter. This provides enhanced multi-path performance and reduced complexity in comparison to the use of two generators and independent encoding of the I and Q channels. The scramble sequence also provides added multi-path immunity.

[0015] One possible implementation of an encoder in accordance with the present invention is illustrated in Figure 1. Incoming data are first encoded in a BCC encoder 10 (e.g., a rate 1/2 encoder) with a binary convolutional code that is well suited for difficult channels such as wireless communications channels. An example of such a code is described in detail below, although it should be appreciated that the present invention also applies to other codes that will be apparent to those skilled in the art. The encoded data are scrambled using, e.g., a QPSK scramble map 12, before transmission through the communication channel. The QPSK scramble map is responsive to a scramble pattern generator 14, such as a pseudo-random sequence generator, for scrambling the encoded data from the encoder 10. As will be appreciated by those skilled in the art, the encoder of Figure 1 outputs two bits (QPSK) for every one bit input, thus implementing the rate 1/2.

[0016] A binary convolutional code that can be used, for example, is a 64-state, rate 1/2 code. The generator matrix "G" for one such code is given as

$$G = [D^6 + D^4 + D^3 + D + 1, D^6 + D^5 + D^4 + D^3 + D^2 + 1]$$

50

or in octal notation, it is given by  $G = [133, 175]$ . This code provides a good trade-off between additive white Gaussian noise (AWGN) performance and performance in multi-path environments.

[0017] The data used in this scheme may be continuous or packet based. If the invention is used in a packet-based system, then the encoder is placed in a known state at the beginning and the end of every packet. This prevents the data bits near the end of the packet from being substantially less reliable than those early on in the packet. To place the encoder in a known state at the beginning of a packet, the  $M$  memory elements of the convolutional encoder (e.g., the six memory elements 20 described below in connection with Figure 2) are loaded with predetermined values that are

typically all zeros. To place the encoder in a known state at the end of a packet,  $M$  (e.g., six) deterministic bits are input immediately following the last data bit input to the convolutional encoder. These bits are typically all zero, which places the encoder in the zero state.

[0018] A block diagram of one possible implementation of BCC rate  $1/2$  encoder 10 is shown in Figure 2. The illustrated encoder consists of six memory (i.e., delay) elements designated by reference numeral 20. For every data bit input at input terminal 22, two output bits are generated at terminals 24, 26. Modulo-2 adders 30 are connected to specific outputs of the memory element stages to implement the desired generator matrix, which in the case illustrated by Figure 2 is  $G = [133, 175]$ . Thus, as illustrated, adders 30 are provided at stages  $D$ ,  $D^3$ ,  $D^4$ , and  $D^6$  to implement  $G=133$  and adders 30 are provided at stages  $D^2$ ,  $D^3$ ,  $D^4$ ,  $D^5$ , and  $D^6$  to implement  $G=175$ .

[0019] The output of the binary convolutional code is mapped to a constellation using one of two possible modes. One mode uses quadrature phase shift keying (QPSK), as shown in Figure 3, and the other uses binary phase shift keying (BPSK) as shown in Figure 4. In the QPSK mode, each pair of output bits (00, 01, 10, 11) from the binary convolutional code is used to produce one symbol, while in the BPSK mode, each pair of bits from the BCC is taken serially and used to produce two PSK symbols. This yields a throughput of one bit per symbol in QPSK mode and one-half a bit per symbol in BPSK mode.

[0020] The mapping from BCC outputs to PSK constellation points in the BPSK and QPSK modes is determined by a pseudo-random scramble sequence generated by scramble pattern generator 14 (Figure 1). If the value of the scramble sequence is equal to one, then the constellation is rotated counter-clockwise by ninety degrees relative to the constellation that is provided for a scramble sequence value of zero. This is shown for the QPSK mode in Figure 3 and for the BPSK mode in Figure 4. More particularly, it can be seen from the figures that the constellation for  $S=1$  is rotated by ninety degrees with respect to the corresponding constellation for  $S=0$ . It should be appreciated that other implementations can be provided where, e.g., the constellation is rotated in a clockwise direction instead of a counterclockwise direction, or in which rotations of other than  $90^\circ$  are used.

[0021] The pseudo-random scramble sequence is generated from a seed sequence. The seed sequence can comprise, for example, the 16-bit sequence 0011001110001011, where the first bit of the sequence in time is the left most bit. This sequence in octal notation is given as 150714, where the least significant bit is the first in time. This seed sequence is used to generate the pseudo-random scramble sequence of length 256 bits that is used in the mapping of the current PSK symbol. It is the current binary value of this sequence at every given point in time that is taken as "S" in Figures 3 and 4.

[0022] This sequence of 256 bits is produced by taking the first sixteen bits of the sequence as the seed sequence, the second sixteen bits as the seed sequence cyclically left rotated by three, the third sixteen bits as the seed sequence cyclically left rotated by six, etc. If  $c_i$  is the  $i$ th bit of the seed sequence, where  $0 \leq i \leq 15$ , then the sequence that is used to scramble the data are given row-wise as follows:

35      c0 c1 c2 c3 c4 c5 c6 c7 c8 c9 c10 c11 c12 c13 c14 c15  
       c3 c4 c5 c6 c7 c8 c9 c10 c11 c12 c13 c14 c15 c0 c1 c2  
       c6 c7 c8 c9 c10 c11 c12 c13 c14 c15 c0 c1 c2 c3 c4 c5  
       ...  
       c10 c11 c12 c13 c14 c15 c0 c1 c2 c3 c4 c5 c6 c7 c8 c9  
 40      c13 c14 c15 c0 c1 c2 c3 c4 c5 c6 c7 c8 c9 c10 c11 c12

For packet based systems with more than 256 bits and continuous systems, this sequence of 256 bits is simply repeated.

[0023] Figures 5 to 7 illustrate another embodiment in which a 256-state, rate  $2/3$  code is implemented. Such an embodiment can be used to provide, for example, a 22 Mbps PBCC. Referring to Figure 5, incoming data are first encoded in a rate  $2/3$  BCC encoder 50. The encoded data are scrambled using, e.g., an 8PSK scramble map 52, before transmission through the communication channel. The 8PSK scramble map is responsive to a scramble pattern generator 14, which can be identical to that described above in connection with the rate  $1/2$  QPSK embodiment of Figure 1. As will be appreciated by those skilled in the art, the encoder of Figure 5 outputs three bits (8PSK) for every two bits input, thus implementing the rate  $2/3$ .

[0024] The generator matrix "G" for the rate  $2/3$  code can comprise:

$$55 \quad G(D) = \begin{bmatrix} D^4 + 1 & D & D^3 + D \\ D^3 & D^4 + D^2 + 1 & D^3 + D \end{bmatrix}$$

[0025] In octal notation, this matrix is defined as

$$5 \quad G = \begin{pmatrix} 21, 02, 12 \\ 10, 25, 12 \end{pmatrix}.$$

[0026] A block diagram illustrating one possible implementation for the BCC rate 2/3 encoder 50 is illustrated in Figure 6. The illustrated encoder consists of separate paths for the two input bits  $m_0$  (the least significant bit) and  $m_1$  (the most significant bit). The path for  $m_0$  comprises four delay elements 60, which can simply comprise memory registers as well known in the art. The path for  $m_1$  comprises four additional delay elements 62. As indicated above, for every two bits ( $m_0, m_1$ ) input, three bits are generated at the encoder output. The three output bits are designated  $x_0, x_1$  and  $x_2$ , where  $x_0$  is the least significant bit (lsb) and  $x_2$  is the most significant bit (msb). Modulo-2 adders 64 are connected to specific outputs of the delay elements to implement the desired generator matrix which, in the case illustrated by Figure 15, is represented in octal as

$$20 \quad G = \begin{pmatrix} 21, 02, 12 \\ 10, 25, 12 \end{pmatrix}.$$

[0027] The output of the BCC is mapped to a constellation using, e.g., 8PSK. An example 8PSK constellation is shown in Figure 7. Each triplet of output bits (000, 001, 010, 011, 100, 101, 110 and 111) from the BCC is used to produce one symbol. As with the embodiments of Figures 1-4, the mapping from BCC outputs to PSK constellation points in the 8PSK mode is determined by the pseudo-random scramble sequence generated by scramble pattern generator 14. If the value of the scramble sequence is equal to one, then the constellation is rotated, e.g., counterclockwise by ninety degrees relative to the constellation that is provided for a scramble sequence value of zero. As shown in Figure 7, the constellation for  $S=1$  is rotated by ninety degrees with respect to the corresponding constellation for  $S=0$ . The pseudo-random sequence can be the same as described above in connection with the embodiments of Figures 1-4.

[0028] It should now be appreciated that the present invention provides various new and unique binary convolutional coding schemes. Moreover, an inventive scheme is disclosed for scrambling the encoded data prior to transmission over a communication channel. The scrambling assures that delayed versions of the codeword will not "look" like codewords to the receiver. Instead, they will look like uncorrelated noise, which improves multi-path immunity. A PN-sequence generator can be easily implemented for use in providing the scramble sequence. It is noted that long scramble sequences will improve performance with respect to co-channel interference. . .

[0029] The invention further provides new BCC generator structures, which can advantageously be used with the disclosed scramble sequence. Moreover, long sequences are generated from a shorter seed sequence through cyclic shifts. The concept of scrambling by rotating the constellation (e.g., by 90°) is also unique.

[0030] Although the invention has been described in connection with various preferred embodiments, it should be appreciated that numerous modifications and adaptations may be made thereto without departing from the scope of the invention as set forth in the claims.

### Claims

45 1. A method for convolutionally encoding digital data for transmission over a communication channel, comprising the step of:

50 processing said data using one of a 64-state, rate 1/2 binary convolutional code (BCC) based on octal generators 133, 175 or a 256-state, rate 2/3 BCC based on octal generators

$$\begin{pmatrix} 21, 02, 12 \\ 10, 25, 12 \end{pmatrix}$$

55 to provide binary convolutional coded codewords.

2. A method in accordance with claim 1 comprising the further step of:

scrambling said codewords prior to transmission over said communication channel.

3. A method in accordance with claim 2 wherein said codewords are encoded jointly onto in-phase (I) and quadrature (Q) channels.

5 4. A method in accordance with claim 2 or 3 wherein:

10 said codewords are mapped to a constellation according to a pseudo-random scramble sequence comprising bits having one of first and second binary values;

15 in the event a bit of the scramble sequence has said first binary value, maintaining said constellation in a current relationship with respect to constellation axes; and

20 in the event a bit of the scramble sequence has said second binary value, rotating said constellation by ninety degrees.

25 5. A method in accordance with claim 4, wherein said constellation is rotated counterclockwise in the event said bit of the scramble sequence has said second binary value.

6. A method in accordance with claim 4 or 5 wherein said scramble sequence is generated from a seed sequence 0011001110001011, where the first bit of the sequence in time is the left most bit.

20 7. Apparatus for encoding data for use in digital communications systems comprising:

25 a binary convolutional encoder; and

30 a scrambler for scrambling codewords provided by said encoder prior to transmission over a communication channel.

8. Apparatus in accordance with claim 7, wherein said scrambler is responsive to a scramble pattern generator.

9. Apparatus in accordance with claim 7 or 8 wherein said codewords are encoded jointly onto in-phase (I) and quadrature (Q) channels.

35 10. Apparatus in accordance with one of claims 7 to 9 wherein:

35 said codewords are mapped to a constellation according to a pseudo-random scramble sequence comprising bits having one of first and second binary values;

40 in the event a bit of the scramble sequence has said first binary value, maintaining said constellation in a current relationship with respect to constellation axes; and

45 in the event a bit of the scramble sequence has said second binary value, rotating said constellation.

50 11. Apparatus in accordance with claim 10, wherein said constellation is rotated counterclockwise in the event said bit of the scramble sequence has said second binary value.

12. Apparatus in accordance with claim 11, wherein said counterclockwise rotation comprises a ninety degree rotation.

55 13. A method for encoding data for use in digital communications systems comprising the steps of:

55 encoding data to be communicated over a communication channel using a binary convolutional code; and  
scrambling codewords provided by said binary convolutional code prior to transmission over said communication channel.

14. A method in accordance with claim 13 comprising the further step of encoding said codewords jointly onto in-phase (I) and quadrature (Q) channels.

55 15. A method in accordance with claim 13 or 14 comprising the further steps of:

55 mapping said codewords to a constellation according to a pseudo-random scramble sequence comprising bits having one of first and second binary values;

60 in the event a bit of the scramble sequence has said first binary value, maintaining said constellation in a cur-

rent relationship with respect to constellation axes; and  
in the event a bit of the scramble sequence has said second binary value, rotating said constellation.

5 16. A method in accordance with claim 15, wherein said constellation is rotated counterclockwise in the event said bit  
of the scramble sequence has said second binary value.

17. A method in accordance with claim 16, wherein said counterclockwise rotation comprises a ninety degree rotation.

18. Apparatus for encoding data for use in digital communications systems comprising:

10 a binary convolutional encoder for processing said data using one of a 64-state, rate 1/2 binary convolutional  
code (BCC) based on octal generators 133, 175 or a 256-state, rate 2/3 BCC based on octal generators

15 
$$\begin{pmatrix} 21,02,12 \\ 10,25,12 \end{pmatrix}$$

to provide binary convolutional coded codewords.

20 19. Apparatus in accordance with claim 18 wherein:

said codewords are mapped to a constellation according to a pseudo-random scramble sequence comprising  
bits having one of first and second binary values;  
in the event a bit of the scramble sequence has said first binary value, maintaining said constellation in a cur-  
25 rent relationship with respect to constellation axes; and  
in the event a bit of the scramble sequence has said second binary value, rotating said constellation.

20 20. Apparatus in accordance with claim 18 or 19 further comprising a scrambler for scrambling codewords provided by  
said encoder prior to transmission over a communication channel.
